BCD TO 7-SEGMENT DECODER

The SN54/74LS48 is a BCD to 7-Segment Decoder consisting of NAND gates, input buffers and seven AND-OR-INVERT gates. Seven NAND gates and one driver are connected in pairs to make BCD data and its complement available to the seven decoding AND-OR-INVERT gates. The remaining NAND gate and three input buffers provide lamp test, blanking input/ripple-blanking input for the LS48.

The circuit accepts 4-bit binary-coded-decimal (BCD) and, depending on the state of the auxiliary inputs, decodes this data to drive other components. The relative positive logic output levels, as well as conditions required at the auxiliary inputs, are shown in the truth tables.

The LS48 circuit incorporates automatic leading and/or trailing edge zero-blanking control (RBI and RBO). Lamp Test (LT) may be activated any time when the BI/RBO node is HIGH. Both devices contain an overriding blanking input (BI) which can be used to control the lamp intensity by varying the frequency and duty cycle of the BI input signal or to inhibit the outputs.

- Lamp Intensity Modulation Capability (BI/RBO)
- Internal Pull-Ups Eliminate Need for External Resistors
- Input Clamp Diodes Eliminate High-Speed Termination Effects

BCD TO 7-SEGMENT DECODER

The SN54/74LS48 is a BCD to 7-Segment Decoder consisting of NAND gates, input buffers and seven AND-OR-INVERT gates. Seven NAND gates and one driver are connected in pairs to make BCD data and its complement available to the seven decoding AND-OR-INVERT gates. The remaining NAND gate and three input buffers provide lamp test, blanking input/ripple-blanking input for the LS48.

The circuit accepts 4-bit binary-coded-decimal (BCD) and, depending on the state of the auxiliary inputs, decodes this data to drive other components. The relative positive logic output levels, as well as conditions required at the auxiliary inputs, are shown in the truth tables.

The LS48 circuit incorporates automatic leading and/or trailing edge zero-blanking control (RBI and RBO). Lamp Test (LT) may be activated any time when the BI/RBO node is HIGH. Both devices contain an overriding blanking input (BI) which can be used to control the lamp intensity by varying the frequency and duty cycle of the BI input signal or to inhibit the outputs.

- Lamp Intensity Modulation Capability (BI/RBO)
- Internal Pull-Ups Eliminate Need for External Resistors
- Input Clamp Diodes Eliminate High-Speed Termination Effects

Condições “Don't care”

- Alguns circuitos possuem certas combinações de entrada para as quais não importa a saída do circuito (ou não existe especificação do nível lógico de saída).
- Ou seja, certas combinações de entradas que não geram impacto na função lógica (a saída pode ir tanto para nível lógico ALTO quanto BAIXO).
- Recebem o nome de termos “don't care”. Na tabela verdade e no mapa, estas condições são registradas usando a letra “X”.
- Exemplo: (segue)...

Multiplexação de Displays

Linhas habilitação de cada display

Problema:

- Projetar um circuito onde o número de leds ativos aumenta conforme aumenta a velocidade da bicicleta.

- Neste circuito um pequeno gerador DC acoplado à roda da bicicleta gera uma saída proporcional a velocidade sendo desenvolvida.
- A saída do gerador DC alimenta a placa de um tacogerador que limita sua tensão de saída se o gerador DC ultrapassar certa tensão. Isto é, mesmo que a velocidade da bicicleta aumente além de certa velocidade máxima, a saída do tacogerador já atingiu seu limite e todos os leds já estarão acesos.
- Um conversor A/D de 3-bits converte a tensão do tacogerador para os bits de saída: A, B e C, onde A=MSB e C=LSB.
- Detalhes: o conjunto de 5 leds deve responder para 6 códigos de saída do A/D. Quando ABC=000, bicicleta sem movimento, nenhum led deve se ativar. Para os seguintes 5 códigos de saída: 001 ~ 101 os leds L1, L2, L3, L4 e L5 devem se ativar conforme a velocidade aumenta. Note que não estamos usando os códigos de saída: 110 e 111 porque se supõe que estes códigos nunca ocorrem uma vez que a faixa de excursão de entrada do A/D foi limitada pela placa do tacogerador.

Problema:

- Projetar um circuito onde o número de leds ativos aumenta conforme aumenta a velocidade da bicicleta.

- Neste circuito um pequeno gerador DC acoplado à roda da bicicleta gera uma saída proporcional a velocidade sendo desenvolvida.
- A saída do gerador DC alimenta a placa de um tacogerador que limita sua tensão de saída se o gerador DC ultrapassar certa tensão. Isto é, mesmo que a velocidade da bicicleta aumente além de certa velocidade máxima, a saída do tacogerador já atingiu seu limite e todos os leds já estarão acesos.
- Um conversor A/D de 3-bits converte a tensão do tacogerador para os bits de saída: A, B e C, onde A=MSB e C=LSB.
- Detalhes: o conjunto de 5 leds deve responder para 6 códigos de saída do A/D. Quando ABC=000, bicicleta sem movimento, nenhum led deve se ativar. Para os seguintes 5 códigos de saída: 001 ~ 101 os leds L1, L2, L3, L4 e L5 devem se ativar conforme a velocidade aumenta. Note que **não estamos usando os códigos de saída: 110 e 111** porque se supõe que estes códigos nunca ocorrem uma vez que a faixa de excursão de entrada do A/D foi limitada pela placa do tacogerador.

Tabela Verdade:

Re	AB	L1	L2	L3	L4	L5
0	000	0	0	0	0	0
1	001	1	0	0	0	0
2	010	1	1	0	0	0
3	011	1	1	1	0	0
4	100	1	1	1	1	0
5	101	1	1	1	1	1
6	110	X	X	X	X	X
7	111	X	X	X	X	X

Solução Possível:

You have to fall,
before you can fly
